Abstract
The parotid duct is formed by the confluence of two ducts in the gland which ascend and descend at right angle to the main duct. While crossing the masseter muscle, it can receive the accessory parotid duct. Although the anatomical course of this duct is well known, the reports on its normal anatomical variations and morphometry are very few. During routine dissection in the Department of Anatomy of Ege University School of Medicine, double parotid ducts were observed bilaterally in a 72-year-old male cadaver. These were traced carefully and neighboring anatomic structures were demonstrated. The two ducts on both sides merged with each other to form the main parotid duct that had a straight course running horizontally towards the anterior border of the masseter muscle. The length of the main parotid duct was 20.02 mm on the right side and 16 mm on the left side. The distance between tragus and the union point of the double ducts was 52 mm on the right side and 58.72 mm on the left side. Detailed morphometry and location of the double parotid ducts are useful for diagnostic and therapeutic luminal procedures.

Keywords: double parotid duct; parotid duct; parotid gland; sialography; Stensen’s duct

Introduction
The parotid gland is the largest salivary gland in the human projecting forwards on the surface of masseter muscle. In 20% of cases, the accessory parotid gland lies between the zygomatic arch above and the parotid duct below. Small ducts from the accessory gland drain into the parotid duct.[1-3]

The parotid duct, also known as the Stensen’s duct after the Danish neuroanatomist Neils Stensen, begins with the confluence of two main tributaries within the anterior part of the gland. It appears at the anterior border of the upper part of the parotid gland and passes across the masseter. The parotid duct turns medially to reach the oral cavity at the anterior border of the muscle. A single duct usually drains the parotid gland.[3,4-6] This duct is formed by the confluence of the two ducts in the gland which ascend and descend at a right angle to the main duct.[6] It can receive the accessory parotid duct while crossing the masseter.[1] The lumen of the parotid duct is about 3 to 4 mm in diameter and its length is about 5 cm.[1,3,4]

Although the anatomical course of this duct is well known, the reports on its normal anatomical variants and morphometry are very few.[1] Understanding the variations of the parotid duct is important for the assessment new diagnostic and therapeutic techniques.[7] Besides, the proper knowledge of the normal topographic anatomy and variations of the parotid duct provides easy understanding of the analysis of radiographic images and computerized tomographic scans used in sialography.[7] The aim of current study was to report a rare anomaly of the parotid duct because of its clinical importance for both diagnostic and therapeutic procedures.

Case Report
During routine dissection in the Department of Anatomy, Ege University School of Medicine, bilateral double parotid ducts were observed in a formalin-fixed 72-year-old male cadaver. The cadaver had no trace of scars, adhesions or signs of trauma or operation. All measurements were taken using a stainless steel caliper with an accuracy of 0.02 mm. The study conforms to the provisions of the Helsinki Declaration of 1964 and all subsequent revisions.

*This study has been presented as a poster at the XXIV International Symposium on Morphological Sciences (ISMS) in Istanbul, Turkey in 2015.
Parotid ducts on both sides were traced carefully and neighboring anatomical structures were demonstrated. The two ducts on both sides merged with each other and formed the main parotid duct. The duct then had a straight course and ran horizontally towards the anterior border of the masseter (Figures 1 and 2). Diameters were measured from the anterior border of the masseter muscle on both sides (Tables 1 and 2).

Discussion
There are few studies on the surface anatomy of the parotid duct based on cadaver dissections and analyzing sialograms. The duplication of the parotid duct as a previously unreported anomaly was observed in the dissection laboratory of Ege University School of Medicine by Aktan et al. (2001). This was a unilateral anomaly, on the right side. The fusion of the upper and lower ducts was outside the gland 4.8 cm beyond their emergence from it. They pierced the buccinator as a single duct. The distance from the union point to the buccinator muscle was 0.7 cm.

Stringer et al. scanned fifty healthy adults using ultrasound to redefine the surface anatomy of the parotid duct. The duct was on the middle half line between the lower border of the tragus and the cheilion in more than 90% of the individuals. The lower duct was in this region.

Bilateral double parotid ducts

in our cadaver also; the upper duct was not crossing, but over this line. Fernandes et al.\(^1\) also reported this rare variation of the parotid duct during a dissection on the right side in a 46-year-old male cadaver. The lengths of the superior and inferior ducts were 26.49 mm and 37.25 mm, respectively.

The presence of double parotid ducts can be explained on the basis of development of the parotid gland. The parotid gland arises from the epithelial lining the primitive oral epithelium as an elongated furrow, spreading back towards the ear. It can be recognized in human embryos about 8 mm long, at the sixth week of gestational age. It runs between the mandibular and maxillary prominences, and then converts into a tube and loses its connection with the epithelium of the mouth except its ventral end. It grows dorsally and invaginates into the adjacent mesenchyme in the cheek region. The tube persists as the parotid duct and its blind ended sprouts to several epithelial branches that proliferate to form secretory portion (acinus) of the gland at the tenth week of gestational week.\(^1,4,9\) In cases with double parotid ducts, the epithelial sprout was bifurcated and each branch invaginated into the adjacent mesenchyme separately. These branches made two variant ducts.\(^6\) Astik and Dave\(^2\) reported double parotid ducts bilaterally in a 50-year-old male cadaver in 2011 during routine dissection. They reported that the cell-matrix interactions and growth factors had importance on morphogenesis and cyto-differentiation of the parotid gland and development of this variation.

The knowledge of the actual dimensions of the excretory ducts is important in duct endoscopy and lithotripsy. This variation also has clinical importance for parotid gland surgery and facial cosmetic surgeries.\(^2\) In CT sialography and CT fistulography, double parotid ducts may be confused with congenital fistula from accessory parotid gland. Additionally, the duct may be severed by a facial laceration and is at risk of iatrogenic injury during facial surgery and injection of botulinum toxin into mas- seter muscle, because of its superficial location.\(^9\) To keep in mind the double parotid duct variation will reduce iatrogenic injury risks and improve diagnosis of parotid duct injury.
